hashi

Bitcoin on Sui, now on mainnet

What Hashi is, the problem it solves, what changed on Sui since mainnet, what it means for you as a developer, and a demo dApp you can try today.

day3-ferry.vercel.app

[KEYS, DOLLARS AND BITCOIN · DAY 3 · SUIHUB LAGOS]

RURU (@MINTING_RURU)

[WHAT HASHI IS]

Lock on Bitcoin, mint on Sui, burn to release.

Your BTC stays on Bitcoin.
hBTC moves on Sui.

Hashi is Sui's native Bitcoin bridge. You send BTC to a Bitcoin address that Sui's validator committee and an independent guardian control together. After 6 confirmations the committee approves it on Sui, and after a 10 minute safety delay hBTC is minted to you, one for one. Burn hBTC and the committee sends the BTC back to Bitcoin.

[WHAT HASHI IS]

The six parts

From Hashi's docs and Move source, with live numbers from Sui mainnet on 11 November.

01 Committee

105 Sui validators sign Bitcoin transactions together with threshold MPC. No single key holds the BTC.

02 Guardian

A second, independent key in every deposit address, and a rate limit out: 50 BTC, refilled about 50 a day.

03 Your address

Every Sui address has its own Bitcoin deposit address, derived from both keys and the Sui address.

04 hBTC

A Sui coin with 8 decimals, minted into your address balance. One hBTC for every BTC held.

05 Delays

6 Bitcoin confirmations, then a 10 minute window to pause a bad approval before anything mints.

06 Governance

No HASHI token. Committee members vote with stake on pauses, minimums and upgrades.

[WHY HASHI]

The problem it solves

Sui, March 2026: Bitcoin is a $1.4T+ asset, and only 0.22% of it (about $3.07B) is used in DeFi.

Before: sell it or wrap it

- Sell BTC to get dollars, and lose the upside
- Or hand it to a custodian for a wrapped token
- Reserves you cannot check yourself
- One company can freeze, lose or misuse it

Hashi: lock it, use it

- BTC stays on Bitcoin, under a validator committee and a guardian
- Borrow against it without selling
- Reserve on chain: 14.43 BTC held = 14.43 hBTC
- Rules in Move, with delays and a pause

[IMPACT ON SUI]

What Hashi brings to Sui

From Sui's launch posts (March and July 2026) and launch coverage on 8 October 2026.

01 BTC, native to Sui

hBTC is a Sui coin any Move contract can hold, secured by Sui's own validators.

02 Institutions

$500M+ committed, 20+ launch partners, Anchorage Digital among them.

03 Lending

AlphaLend, Bluefin, Current, Scallop and Suilend named for day one; NAVI and Fluid too.

04 Dollar loans

Borrow stablecoins such as USDC against BTC, without selling it.

05 Vaults and yield

Concrete and Bluefin vaults, BTC-backed bonds, RWA strategies.

06 Trust layer

CF Benchmarks pricing, Soter insurance, audits by Certora, OtterSec and Asymptotic.

[READ FROM SUI MAINNET]

What changed since mainnet

Hashi's own events on Sui, read on 12 November. Every row can be checked by anyone.

When	What happened	Source
8 Oct 2026	Mainnet announced for October: $500M+, 20+ partners, Anchorage	Sui Basecamp coverage
22 Oct 2026	First BTC deposit recorded and first hBTC minted	Sui mainnet
2 Nov 2026	9.5 BTC in one day, including a single 6 BTC deposit	Sui mainnet
11 Nov 2026	BTC held = hBTC minted: 14.42974424 each	Sui mainnet + Bitcoin
12 Nov 2026	46 deposits, 14.44 BTC minted, 24 holders, 27 withdrawals	Sui mainnet
Today	Minimum 30,000 sats; 105 validators in the committee	Hashi on Sui

[FOR DEVELOPERS]

What Hashi mainnet means for you

The infrastructure is live. The products on top of it are still to be built.

01 Real BTC, real users

Mainnet is open from 30,000 sats. Testnet pairs with Bitcoin Signet for reads.

02 An SDK

@mysten/hashi: read anything, build PTBs your users sign in their own wallet.

03 Just a Sui coin

hBTC is Balance<BTC>. Everything you know about Move and PTBs applies.

04 Contracts own BTC

Any object ID can get a Bitcoin address. BTC paid to it lands in the contract.

05 A shopping list

Partners want BTC-backed loans, vaults and structured products built on Sui.

06 An empty app layer

24 holders so far. Wallet flows, payments and local products are open.

[POSITION YOURSELF]

How to be early on Hashi

Five moves for a Sui developer in Lagos who wants to build Bitcoin products.

01

Learn it

Run Ferry. Read the SDK and Hashi's deposit and withdraw Move code.

02

Build free

Mainnet reads need no BTC. Your Move code runs on testnet.

03

Go local

P2P escrow, payment links, BTC savings, dollar loans against BTC.

04

Plug in

Build on the lending markets and wallets in the launch coalition.

05

Ship it

Tools, dashboards and demos other builders need. Be the name people know.

[A DEMO DAPP]

Ferry: what a Hashi dApp looks like

day3-ferry.vercel.app · built on @mysten/hashi, no server, the user's own Slush wallet.

01

Your address

One Bitcoin address per Sui address, with a QR code and the minimum.

02

Payments

Hashi does not scan Bitcoin. The app finds the outputs that paid you.

03

Record

One PTB, simulated first, then signed in the user's wallet.

04

Track

Confirmations, approval, the delay, the mint. Pending, never failed.

05

Withdraw

Withdraw with the worst-case fee shown first, cancel within the rules.

[@MYSTEN/HASHI 0.6.29]

The whole integration in one screen

The SDK extends any Sui client. view reads, tx builds unsigned PTBs, call gives Move calls.

TYPESCRIPT

```typescript
const client = new SuiGrpcClient({ network: 'mainnet', baseUrl }).$extend(
  hashi({ hashiObjectId, packageId, bitcoinNetwork: 'mainnet' }),  // mainnet: pass the ids
);

client.hashi.generateDepositAddress({ suiAddress })    // your Bitcoin address
client.hashi.view.all()                                // minimums, confirmations, delays, paused
client.hashi.view.depositStatus(digest)                // pending, confirmed, expired
client.hashi.view.transactionHistory(address)          // deposits and withdrawals
client.hashi.view.balance(address)                     // hBTC, in sats
client.hashi.tx.deposit({ txid, utxos, recipient })    // unsigned PTB: the wallet signs
client.hashi.tx.requestWithdrawal({ amount, bitcoinAddress })
client.hashi.guardian.canWithdraw(sats)                // the rate limiter
```

[MOVE/JAR/SOURCES/JAR.MOVE]

A contract with its own Bitcoin address

An object's ID is a Sui address, so Hashi can give it a Bitcoin address and mint hBTC straight into it.

MOVE

```
public struct Jar<phantom T> has key { id: UID, unlock_ms: u64, taken: u64 }

// Hashi mints with balance::send_funds(btc, jar id): the hBTC lands in the jar itself
public fun take<T>(self: &mut Jar<T>, cap: &JarCap<T>, amount: u64, clock: &Clock): Balance<T> {
    assert!(cap.jar_id == self.id.to_inner(), EWrongCap);
    assert!(clock.timestamp_ms() ≥ self.unlock_ms, ELocked);
    balance::redeem_funds(balance::withdraw_funds_from_object<T>(&mut self.id, amount))
}

// TS: client.hashi.generateDepositAddress({ suiAddress: jarId })  →  bc1p890h9...45ne7h
```

[HANDS ON]

Try it now

No BTC needed. Mainnet for reading and following, testnet for your own Move code.

01

Your address

Open day3-ferry.vercel.app, connect Slush: your own Bitcoin address.

02

Follow one

Pick one under "Latest on Hashi mainnet" and follow it to the mint.

03

Reserve

BTC held against hBTC minted, live. Then switch to Testnet.

04

Verify

Clone the repo: pnpm install, then pnpm verify against mainnet.

05

Your jar

Publish move/jar on testnet and get its own Bitcoin address.

[TAKE HOME]

The rails are live. The apps are not built yet.

Bitcoin is what people here already hold. Now it works on Sui.

Hashi gives every Sui address, and every Move object, its own Bitcoin address. Three weeks after mainnet it held 14.44 BTC for 24 holders. Learn the SDK, build on testnet for free, and pick a Bitcoin product for users you understand. Code: github.com/Nuel-osas/day3-ferry.
